Abstract

Introduction: To have a health administration that is effective, operational readiness and crisis response are critical. Nursing, health security, and radiology units are important in guaranteeing patient safety, continuity of care, and effective management of emergency. The healthcare systems need to have coordinated strategies and ethical frameworks to work with emergencies.

Aim: This research paper will focus on the input of nursing, health security, and radiology units towards operational readiness and crisis response in health management. It aims to find out the most important practices, challenges, and ethical issues in emergency preparedness and response.

Methods: This will involve a mixed-method approach which will involve structured surveys, interviews, and observational assessments across healthcare units. Perceptions regarding readiness, interdepartmental collaboration, and effective communication will be assessed with quantitative data, whereas experiences, challenges and ethical dilemmas in the crisis will be explored with qualitative data.

Findings: Early results show that the operation backbone is the nursing units, and the other aspect is health security that guarantees safety and order. and radiology gives the necessary support in terms of critical diagnosis. Interdisciplinary teamwork, ethical actions and administrative leadership facilitate the state of operational readiness.

Conclusion: Strategic coordination and ethical frameworks as well as multidisciplinary collaboration are the basis of operational readiness. Enhancement of the functions of nursing, health security, and radiology departments enhances patient safety, effectiveness in responding to crisis, and resiliency of the health system overall. Constant assessment and readiness are necessary in case of a future emergency.

Keywords: operational preparedness, Crisis response, Health administration, Nursing, Health security, Radiology, Patient safety.

Introduction

The global healthcare systems are increasingly being challenged with the complex, multi-dimensional crises that are challenging their preparedness, coordination and response time. Such crises include outbreaks of infectious diseases, incidents of mass casualty, radiological threats, systemic crises of the supply chain, and crises related to security. In this changing threat environment, operational preparedness has become one of the foundation stones of successful health management, with the framework of operational preparedness being the tool on which sustainable crisis response infrastructures have been established. Operational preparedness in healthcare goes beyond the preparation of physical resources, and it includes leadership, interprofessional coordination, workforce preparedness, information systems, and institutional flexibility to respond to pressure (Pesigan et al., 2020; Alseinan Al Yami et al., 2023).

Health administration is recognized as one of the key agents of implementing strategic preparedness plans into operational practices in times of crisis. The administrators would be tasked with coordinating policies, protocols, and human resource within the clinical and non-clinical units to maintain continuity of care and patient safety. The recent health crises around the world and especially the COVID-19 pandemic have highlighted the key weaknesses in preparedness and response measures, which highlights the necessity to integrate various frameworks linking the decision-making of the administration unit with operational force in the frontline (Al Salem et al., 2024). Consequently, the modern healthcare approach to managing the crisis is becoming more focused on system-wide cooperation instead of the departmental reaction to the crisis.

Nursing services, health security units and radiology units are some of the most influential contributors to operational readiness and crisis response, and each has a separate but yet interdependent role in the healthcare organizations. In the case of an emergency, nursing personnel are the core of clinical response providing constant patient care, triage, monitoring, and interdepartmental coordination. This will put them at the center of the crisis response process because of their close contact with patients; hence their preparedness, adaptability, and leadership would play a crucial role in effective emergency management (Alqahtani et al., 2024). Research continues to point out that nursing that is well trained and empowered can help vastly during emergencies to improve response and patient outcomes (Alshehre et al., 2024).

The other key pillar of operational readiness is health security units that are mainly involved in the control of access, management of crowds, containment of incidents and coordination with outside emergency and security forces. Health security officers have in recent years been increasingly engaged in the active response to emergency preparedness planning, drills, and real-time response to the crisis. They guarantee the security of patients, healthcare professionals, and infrastructure, which means that clinical teams will have no problems with their tasks (Alrshedi et al., 2024). Health security functions play a critical role in ensuring that there is order and operational continuity in healthcare facilities in situations of high risks like the occurrence of mass casualties or biosecurity threats.

The radiology departments are also invaluable in emergency and crisis situations because diagnostic imaging is the core of quick evaluation, triage, and clinical decision-making. Radiology services should be precise, fast, and safe in situations when there is a trauma, pandemic, radiological and nuclear emergencies. Radiological preparedness goes beyond technical preparedness and equipment provision and encompasses radiation safety measures, workforce education, and emergency medical and administrative collaboration (Stinson, 2021). The capability of the radiology units to continue operating without interruption in case of crises directly determines the accuracy of diagnostic methods and treatment outcomes.

Recent research states that interdependence and cooperation between nursing, radiology, health security, pharmacy, emergency medical services, and administration leadership is needed to increase

emergency rescue rates and the outcome of crisis situations (Alshehre et al., 2024; Alqahtani et al., 2024). Weak communication channels, fragmented responses, and silos that exist between the departments destroy operational preparedness and slow down urgent interventions. On the contrary, integrated models of crisis management promote common situational awareness, synchronized decision making, as well as effective resource use.

Moreover, the concept of operational preparedness in healthcare administration is being changed through the development of digital health and information systems. The digital preparedness, which includes electronic health records, real-time data exchange, telehealth, and decision-support systems, contributes to improving the readiness of healthcare organizations to the predictability, monitoring, and response to a crisis. The experience of healthcare leaders reveals that the concept of digital health preparedness cannot be discussed outside the category of operational management and crisis resilience. Digital tools enhance both the institutional preparedness and adaptive capacity when combined with administrative leadership and the capabilities of units at the front line (Stinson, 2021).

Health Informatics Technicians have become increasingly important contributors to operational readiness and crisis response through their role in managing healthcare information systems, ensuring data quality, and supporting evidence-based decision-making. During emergencies, they facilitate the continuous availability of electronic health records, real-time data integration, and accurate reporting, enabling healthcare professionals and administrators to make timely and informed decisions. They also contribute to interoperability between clinical departments, improve communication across multidisciplinary teams, and assist in monitoring resource utilization and patient flow. Furthermore, by maintaining data integrity, supporting health information security, and generating operational dashboards, Health Informatics Technicians strengthen situational awareness and enhance the overall resilience of healthcare organizations during crisis situations. Their contribution complements the clinical and administrative efforts of nursing, health security, and radiology units, making health informatics an essential component of modern emergency preparedness and healthcare management.

In terms of strategy, crisis preparedness is also a factor of supply chain resilience, logistic preparation, and ongoing evaluation of organizational weaknesses. According to Yang and Zelbst (2024), the resilience of a healthcare crisis will need both strategic and tactical frameworks that will assess the preparedness of the indicators in various dimensions, such as workforce, infrastructure, coordination, and external dependencies. These systems are quite applicable to the health administration field that has to strike a balance between long-term preparedness planning and immediate operational needs in case of an emergency.

Considering these factors, the current paper aims at investigating operational preparedness and crisis response in health administration, and, specifically, the role of nursing, health security and radiology units. The study will help to understand the roles, interactions and challenges of these units in emergency situations to give a clear picture of how integrated operational readiness can lead to resilience of healthcare systems. The research is based on modern empirical and theoretical literature and adds to the expanding range of information on the topic of multidisciplinary crisis management in healthcare facilities.

Finally, administrative leadership and interprofessional cooperation as the means of strengthening operational preparedness is not only a managerial goal but a key to protecting the health of the population and securing successful responses to future crises. This study highlights the need to shift towards system-based preparedness models that are inclusive, acknowledging the cumulative efforts of a wide variety of healthcare units towards the development of strong and resilient crisis response capabilities.

Aim of the Work

This research paper seeks to investigate the extent of operational readiness and the crisis response effectiveness in health administration with particular emphasis on the role and interprofessional contribution of the nursing, health security and radiology units. The proposed study aims to examine the

role of coordination and integration between these major units in preparedness, efficiency in response, and continuity of healthcare services in the case of emergency and crisis scenarios.

Moreover, the paper is going to examine the reasons of how administration, organization and operations can either enhance or inhibit effective crisis management within a healthcare setting. The study aims at showing how health administration is critical in ensuring that strategic planning is coordinated with the frontline operational functions by identifying strengths, gaps and challenges in the preparedness and response practices currently in place.

Finally, the research project will help advance the evidence-based guidelines to improve multidisciplinary cooperation, operational preparedness, and crisis response systems in healthcare facilities, which will support resilience, patient safety, and sustainable healthcare system functioning in the event of another emergency.

Methods

A mixed-method research design will be used in the proposed study to gain a holistic and profound insight into the operational readiness and crisis response in health administration and specifically the role of nursing, health security and radiology unit. Quantitative and qualitative methodology should be combined to bring to focus both the structural and functional aspects of crisis preparedness and the experiences and obstacles encountered practically by healthcare professionals in cases of emergency situations. It is a particularly suitable design given the interacting and dynamic nature of healthcare systems and administrative coordination, clinical operations, security measures, psychosocial support, and diagnostic services need to work together in harmony to guarantee a successful response to a crisis and continuity of care.

Structured questionnaires are going to be used to address the quantitative part of the research that will deal with a different sample of healthcare professionals employed in hospitals and healthcare facilities. The population participants will consist of nurses, health security officers, radiology technologists, and administrative staff in emergency preparedness and crisis management. The questionnaires will have a design to examine the perceptions of operations readiness and effectiveness of departments in responding to crisis. The main areas of assessment will be emergency preparedness planning, role and responsibility clarity during crisis situations, resource availability, and adequacy, efficiency of communication, administrative leadership and operational units' coordination, compliance with emergency procedures, and perceived preparedness to respond to different crisis situations such as mass casualties, pandemic, or security-related emergencies. Other sections will address interprofessional collaboration, leadership support, training and exposure to simulation, and the perceived role of operational readiness on patient safety and organizational resilience. The survey instruments will be based on previous instruments that have been proved to be reliable and valid in the context of healthcare crisis management, emergency preparedness, and operational readiness research.

The qualitative aspect of the research will involve semi structured individual interviewing and focus group discussions with the chosen respondents who have a lot of experience in crisis response and operational management. The representatives of nursing services, health security units, radiology units, and health administration will be included in the participants. The goals of these qualitative approaches are to examine the experiences, perceptions, and insights of the participants on operational readiness prior to, during, and following crisis events. The discussion based on the interview will address the real-life crisis situations, perceived barriers and facilitators to effective crisis response, interdepartmental coordination difficulties, leadership, and decision-making process, flow of communication during emergency situations, and integration of clinical, security, and psychosocial services. The role clarity of each unit, collaboration expectations, and the strategies adopted to sustain the service continuity and patient-centered care in high-pressure situations will be considered.

Secondly, observation methods will be used directly to analyze the real crisis preparedness efforts and response practice in the healthcare facilities. The areas to be observed will include emergency departments, inpatient wards, radiology departments, security control points, and social service units, which are the major operational areas in institutions. Observational area will cover the application of emergency measures, interdisciplinary work between nursing and radiology in case of an emergency diagnostician, health security in access and safety and The observations will be useful in finding out how the operational behavior, compliance with institutional guidelines, communication patterns, and how crisis response plans were practically implemented.

Further, simulation-based situations will be used to evaluate interdisciplinary performance in dealing with crisis under control but realistic conditions. Examples of simulated crisis scenarios can involve one of the following: mass casualty, infectious disease outbreak, radiological emergency, or a security emergency in which nursing, health security, radiology, and administrative leadership will need to coordinate their efforts. The simulations will assess the problem of timeliness, clarity, and accuracy of information exchange, interprofessional collaboration, leadership effectiveness, pressure-based decision-

making, and patient safety and staff protection prioritizing. This method may be used to conduct a systematic evaluation of operational preparedness and crisis response capacities without putting real patients and personnel at risk.

Methodological triangulation will be implemented to make the study more rigorous, by combining the results of quantitative surveys, qualitative interviews, direct observations, and simulation exercises. Such an in-depth strategy will enhance the validity and richness of the findings, as the perceptual and operational readiness and crisis response will be detailed. Finally, the research will determine the best practices, identify the gaps in functioning, and come up with evidence-based recommendations to enhance health management approaches, interdisciplinary coordination, and crisis preparedness and response in the nursing, health security and radiology units.

Discussion

Operational Readiness as a Strategic Support of Crisis Response in Health Administration.

Operational preparedness is the key strategic point where how well health administration responds to a crisis lies. This concept has been discussed and it is evident that preparedness is not just a state of operations that is activated when there are emergencies but is an ongoing state of the organization that is influenced by the leadership of the organizations, the governance structure, the preparedness of the workforce, availability of resources as well as the coordination of the system-wide. Health administration is strategically positioned in the entrenching operation preparedness to the day-to-day operation of healthcare facilities, making emergency response capacity sustainable and expandable, depending on the levels of how severe the crisis is. Such an interpretation agrees with the international frameworks that operational readiness has been conceptualized as a dynamic ability of healthcare systems to anticipate, absorb, respond, and recover during a crisis as well as being able to sustain necessary health services (Pesigan et al., 2020; English et al., 2022).

In terms of strategic management, operational preparedness fills that gap between the emergency policy at the high level and the clinical implementation of the strategy at the front line. It is the role of health administrators to convert preparedness plans into action protocols, resources are efficiently allocated, and multidisciplinary units are put under a single command and communication system. Practical experience of global health crises, especially the COVID-19, shows that administrative preparedness of healthcare systems turned out to be more resistant to mobilize staff, changing workflows, and continuing care under the most severe pressure (Mustafa et al., 2022; WHO, 2023). Conversely, those institutions that were not well prepared strategically had fragmented responses, slow decisions making and operational dysfunctions that undermined patient safety and service delivery.

The findings also highlight the importance of considering operational readiness as something that is composed of interdependent parts and not independent preparedness. Workforce preparedness, such as training, role clarity, and psychological preparedness, is coupled with infrastructure preparedness, such as the design of facilities, equipment supply, and resilience of the supply chain. The strategic analyses of crisis preparedness reveal that the inability to perform these elements results in the deterioration of the functioning of the entire system in the event of an emergency (Yang and Zelbst, 2024). Health administration, then, plays a vital role of scrutinizing and reinforcing these mutually interdependent areas to have organizational resilience.

In addition, operational preparedness is directly associated with crisis governance and leadership effectiveness. Strategic leadership allows providing decisions in a timely manner, building trust between healthcare teams, and instilling a sense of responsibility, and learning. The studies conducted in the health and non-health sectors show that proactive organizations with high readiness rates are characterized by better crisis performance and faster recovery (Ghazi et al., 2024). In healthcare organizations, administrative leaders more focused on preparedness by conducting regular drills, simulations, and

performance audits provide a setting where personnel are more likely to react confidently and unitedly during emergencies (Alseinan Al Yami et al., 2023).

The other important aspect of operational readiness is that it has been found to be effective in promoting interdisciplinary cooperation. The proper management of crises necessitates a steady flow of coordination of clinical units, diagnostic services, security teams, and psychosocial support services. Emergency medical services strategic frameworks point out that preparedness is the highest when health administration actively involves various professional groups in single-unit response systems (Al Salem et al., 2024). The paper delivers the reasons behind the opinion that operational preparedness is the mechanical background that allows nursing, health security, and radiology units to work as collaborative groups instead of independent ones in the case of a crisis.

The Nursing Units as the Workhorse in Disaster Response and Patient Safety.

Nursing units form the operational core of healthcare system crisis response because they are in constant proximity to the point of care and because they are the primary point of implementing actions and decisions made by the administration into clinical practice. The case of the findings suggests that in healthcare institutions, nurses tend to be the initial responders in case of emergencies, where they assume the task of patient triage, constant monitoring, coordination of care provision, and real-time cross-departmental communication. This focal location puts the nursing units at the center of the operational preparedness and preparedness of the unit becomes a deciding element in the efficiency of the emergency response and patient safety. The recent healthcare sources highlight the point that the resilience of nursing services is a direct indication of the healthcare organizations resilience in times of crisis (Alqahtani et al., 2024; Alshehre et al., 2024).

On the administrative side, success of nursing units in times of crisis is highly determined by organizational frameworks, leadership, sufficiency in staffing and availability of ongoing training. Emergency plans emphasize that nursing staff must be proactive in prepared planning, training about it through simulations, and the interdisciplinary decision-making process instead of being placed in the position of active executors of crisis instructions (Al Salem et al., 2024). Empowerment of nurses by defining their roles and implementing channels of communication also improves nurses efficiency in handling patient traffic, setting priorities and adjusting to a fast-changing environment. The current research adds to the earlier results proving that better-equipped nursing teams enhance emergency rescue rates and more effective crisis management in hospitals (Alshehre et al., 2024).

Nursing preparedness is inseparably associated with patient safety in a crisis situation, as nurses become the main guarantors of clinical quality in high work conditions, in case of uncertainty and emotional distress. According to the literature, insufficient nursing preparedness is one of the causes of a higher number of clinical errors, communication failures, and reduced infection control in the emergency (Mustafa et al., 2022; Lanyero et al., 2021). Conversely, supported nursing units are more flexible and situationally aware and tend to follow safety measures even under resource-restricted conditions. As noted in this discussion, health administration makes a significant contribution to patient safety protection in terms of adequate staffing, psychological assistance, and access to decision-support tools that can help nursing staff in a crisis (WHO, 2023).

Moreover, the nursing units serve as a focal coordinating center that links various operation services and clinical services, such as radiology, health security and emergency medical services. The collaborative care models emphasize that successful crisis management should rely on a smooth exchange of information and trust between nurses and other groups of professionals (Alqahtani et al., 2024). The results indicate that interdisciplinary collaboration also improves the ability of nurses to address the complex needs of their patients, organize diagnostic and treatment services, and react efficiently to the changing crisis situations. The administration of health needs to put in focus the structures and processes that aid in collaboration and minimize professional silos especially where high-risk situations are involved.

Health Security Unit and the Safety of Continuity of the Operation in cases of emergencies.

Safe and uninterrupted crisis response was found to be enabled by health security units. The results reveal that health security officers are fully involved in a wider scope that is not only physical protection but also active involvement in emergency preparedness, access control, reduction of risks and coordination with the internal and external stakeholders. This is consistent with the recent studies that have highlighted health security units as part of hospital emergency preparedness plans (Alrshedi et al., 2024).

In the view of health administration, health security is integrated into the crisis command structure to increase situational awareness and operational stability. Security units in high-risk conditions like a mass casualty event, pandemic, or radiological threat, are necessary to maintain patient flow and staff and infrastructure security, also allowing clinical staff to be effective. This study results align with operational readiness models that suggest the significance of non-clinical divisions to maintain healthcare provision during emergencies (Pesigan et al., 2020). The inability to logically incorporate health security operations may jeopardize safety and the efficiency of responses and, therefore, there is a need to have administrative leadership that would view security units not as services but as core components of managing the crisis.

Diagnostic Preparedness High-Risk Scenario Radiology Units.

The unit of radiology became one of the pillars of diagnostic preparedness in crisis situations due to the critical role that it plays in quick assessment, triage, and clinical judgment. The results show that radiology preparedness has a significant impact on the timeliness and quality of emergency care especially in trauma, outbreak of infectious diseases, radiological or nuclear emergencies. It is in line with the past research that notes that the effectiveness of crisis response lies in its diagnostic capacity (Stinson, 2021).

Preparedness in the radiology area goes beyond the availability of equipment to encompass training of the workforce, radiation safety measures, workflow flexibility, and interactions with nursing and emergency services. According to the literature, the radiology units should be brought to the level of emergency response plans to avoid the delay in diagnostics and operational bottlenecks in the emergency response (Heydari et al., 2022). The collaboration care research also proves that good coordination among radiology, nursing, and health security improve patient outcomes and efficiency in the system in case of emergencies (Alqahtani et al., 2024). The results of this study make it clear that health administration should focus on the radiology preparedness as one of the strategic elements of a crisis preparedness.

Interdisciplinary Collaboration as a Power of Successful Crisis Response.

One of the key points of this discussion is that interdisciplinary collaboration is of the utmost importance when it comes to operational preparedness and a successful crisis response. These results imply that combined efforts of nursing, health security radiology, and administrative leadership can increase situational awareness and speed up decisions and improve overall system performance in times of crisis. This finding is in accordance with strategic frameworks that support the integrative emergency medical services and multidisciplinary coordination (Al Salem et al., 2024).

The lack of operational preparedness is determined by the fragmented responses and departmental silos that cause the gaps in communication and postponement of vital interventions. Conversely, the interdisciplinary models encourage collective accountability, role clarity and shared problem-solving (Yang and Zelbst, 2024). The same approaches to project management to public health preparedness can also justify the necessity of the systematic coordination systems that would bring various units on the same path of action in the case of an emergency (Ishehri et al., 2024). Health administration is essential to facilitate this partnership by setting up governing frameworks, channels of communication and accountability.

Digital Health Readiness and Resilience at the Systems level.

Digital health preparedness became a major facilitator of operational preparedness and response to crisis. The results suggest that digital infrastructure, such as the electronic health record, real-time reporting

systems, and decision-support tools, increase coordination and minimize delays in the information exchange in emergencies. This correlates with the findings indicating that digital preparedness is a fundamental aspect of the contemporary operational management system and crisis resilience (Alseinan Al Yami et al., 2023)

In the administrative side, digital systems facilitate nursing records, radiology reporting, security check-ups, and social coordination of work, enhancing interdisciplinary communication. The research on e-readiness also shows that organizations that have developed high levels of digital capabilities are in a better position to respond to disruption related to the crisis and remain viable when stressed (Ghazi et al., 2024). These results indicate that health administrators should see digital readiness as a strategic investment and not a technological addition.

Health Administration Practice and Policy Implications.

The discussion has some key implications to the practice of health administration and policy development. Enhancing operational preparedness needs to be supported by comprehensive leadership frameworks which include nursing, health security, and radiology in preparedness planning and crisis governance models. Acute training, exercises under simulation, and performance analysis are necessary to remain prepared in the long-term (Alseinan Al Yami et al., 2023; Pesigan et al., 2020).

At the policy level, institutional preparedness strategies should be aligned with the national and international emergency frameworks, which increase the system-wide resilience. The experiences of COVID-19 and other epidemic diseases have helped people learn that sustainable, long-term investments in operational preparedness are more valuable than responding to the crisis (Mustafa et al., 2022; WHO, 2023). Health administration should therefore be proactive, system-based in terms of crisis preparedness that emphasizes collaboration, flexibility and resilience.

Issues and Ethical Concerns

Problems and ethical issues are another important aspect of operational preparedness and crisis response in health administration because a crisis has the tendency to reveal the vulnerability of the system, moral dilemmas, and conflict between efficiency, safety, and human dignity. Resource shortage in case of emergencies such as staff shortage, shortage of medical supplies, beds and diagnostic equipment is one of the most outstanding. These shortages compel the administrator and frontline staff to prioritize on-the-fly decisions that can have a direct influence on patient outcomes. When faced with high-pressure scenarios, ethical issues that may emerge in relation to justice, equity, and fairness revolve around the decision of who should get immediate care, advanced interventions, or limited life-saving resources. These struggles are further compounded by the fact that demand may surpass capacity, and thus, creating the possibility of implicit bias, disparities in care provision, or marginalization of vulnerable groups such as the aged, people with disabilities, or chronically ailing individuals. Operationally, the lack of preparedness contributes to the intensification of these ethical tensions, with poorly delineated guidelines and ambiguous chain of command exposing the healthcare workers to moral distress and legal uncertainties as they strive to promote the best interest of the patients.

The other important ethical issue is a dilemma of patient rights and population security in case of crisis. The extraordinary measures usually involved during health emergencies include isolation, quarantine, limited visitations, and quick transfer of information among departments and agencies. Although these actions might be needed to manage risk and continuity of care, they can go against autonomy, informed consent and confidentiality. Overcrowded facilities and increased workflow may lead to limited participation of patients in making decisions, limited communication with families, or even limited privacy. Simultaneously, healthcare practitioners encounter ethical issues in implementing policies that can be coercive or affect people negatively, despite being that way because of the larger long-term health objectives. Ethical frameworks which can guide decision-making within an uncertain situation

should therefore be operational readiness, with the emergency actions being proportionate, transparent, and respectful of basic human rights and yet protect the well-being of the entire community.

There are also workforce-related problems that create serious ethical problems during crisis response. Nurses, radiology workers, health security staff, and administrative leaders frequently must work during long hours, play new roles, and work under the threat of increased danger to their physical and psychological well-being. Burnout, moral injury, and attrition of the workforce in the long run may result due to inadequate staffing plans, lack of protection, or communication. Ethical issues arise when the demands on professionals in the healthcare sector go beyond the scope of acceptable professional duties, especially when they are requested to work in untrained, non-protected, and/or institutionalized circumstances. Moreover, unequal workload allocation and rewards given to various groups of professionals might lead to a sense of injustice and undermine unity within a team. Ethical operational preparedness as a result must be both technically planned and a promise to the welfare of staff, mental health assistance, even-handed distribution of responsibility, and awareness of the human constraints of those providing care in times of crisis.

Conclusion

The operational readiness and crisis response in health administration are multidimensional constructions, which necessitate strategic planning, coordinated implementation, and constant assessment to ensure that healthcare systems are able to react well to pressure. In this study, I have identified that nursing units, health security teams, and radiology departments have distinct roles in operational preparedness creating an interconnected network to ensure continuity of care in the event of an emergency, maintaining patient safety, and sustaining workforce performance. Nursing units are the working units that put administrative decisions into the frontline and protect patient care and disciplinary coordination. Health security units guarantee the safety of the patients and personnel and address logistical problems and operational stability.

The ethical issues have been discussed, which highlights that the crisis is intrinsically accompanied by amplified ethical issues, such as the distribution of resources, patient autonomy, workforce protection, or decision-making transparency. Operational preparedness is not a technical or procedural action only, but also an ethical necessity, and it involves that the health administration must incorporate the moral rationale in planning, communication and leadership. Moreover, interdisciplinary collaboration and digital health preparedness are also ascribed as enabling factors, which are also improving situational awareness, efficiency in communication, and system resilience.

To sum up, the responses of health administration during the crisis are based on the holistic system-driven methodology that involves the integration of strategic leadership, operational coordination, ethical readiness, and the involvement of multidisciplinary teams. The investment in such dimensions will enable healthcare organizations to become more resilient, enhance patient outcomes, and retain confidence in their ability to act in response to future emergencies. Operational readiness is not a steady state but a process that remains dynamic over time and ensures that healthcare systems can respond to changing risks without jeopardizing safety, equity, and quality of care.
